## Algebra - Basic Definitions

## What is an Equation

An equation says that two things are equal. It will have an equals sign " $=$ " like this:

$$
x+2=6
$$

That equation says: what is on the left $(x+2)$ is equal to what is on the right (6)
So an equation is like a statement "this equals that"

## Parts of an Equation

So that people can discuss equations, there are names for different parts (better than saying "that thingy there"!)

Here we have an equation that says $4 x-7$ equals 5 , and all its parts:

A Variable is a symbol for a number we don't know yet. It is usually a letter like x or y .

A number on its own is called a Constant.
A Coefficient is a number used to multiply a variable ( 4 x means 4 times $x$, so 4 is a coefficient)

An Operator is a symbol (such as,$+ x$, etc) that represents an operation (ie you want to do something with the values).

A Term is either a single number or a variable, or numbers and variables multiplied together.

An Expression is a group of terms (the terms are separated by + or - signs)

So, now we can say things like "that expression has only two terms", or "the second term is a constant", or even "are you sure the coefficient is really 4?"

## Exponent!

The exponent (such as the 2 in $x^{2}$ ) says how many times to use the value in
a multiplication.
(or index,
or power)
Examples:
$\mathbf{8}^{\mathbf{2}=\mathbf{8} \times \mathbf{8}=\mathbf{6 4}}$
$\mathbf{y}^{\mathbf{3}=\mathbf{y} \times \mathbf{y} \times \mathbf{y}}$
$\mathbf{y}^{\mathbf{2} \mathbf{z}=\mathbf{y} \times \mathbf{y} \times \mathbf{z}}$

Exponents make it easier to write and use many multiplications
Example: $\mathbf{y}^{4} \mathbf{z}^{\mathbf{2}}$ is easier than $\mathbf{y} \times \mathbf{y} \times \mathbf{y} \times \mathbf{y} \times \mathbf{z} \times \mathbf{z}$, or even $\mathbf{y y y y z z}$

## Polynomial

Example of a Polynomial: $\mathbf{3 \mathbf { x } ^ { 2 }} \mathbf{+ x} \mathbf{- 2}$
A polynomial can have constants, variables and the exponents $\mathbf{0 , 1 , 2 , 3}, \ldots$
And they can be combined using addition, subtraction and multiplication, ... but not division!

A Polynomial

Not Polynomials

## Monomial, Binomial, Trinomial

There are special names for polynomials with 1,2 or 3 terms:

| $3 x y^{2}$ | $5 x-1$ | $3 x+5 y^{2}-3$ |
| :---: | :---: | :---: |
| Monomial (1 term) | Binomial (2 terms) | Trinomial (3 terms) |

## Like Terms

"Like terms" are terms whose variables (and their exponents such as the 2 in $x^{2}$ ) are the same.
In other words, terms that are "like" each other. (Note: the coefficients can be different)

## Examples:

| Terms |  |  |
| :---: | :---: | :---: |
| $7 x$ | $x$ | $-2 x$ |
| $(1 / 3) x y^{2}$ | $-2 x y^{2}$ | $6 x y^{2}$ |

Why are they "Like Terms"
because the variables are all $\mathbf{x}$
because the variables are all $\mathbf{x y}^{\mathbf{2}}$

You can add like terms together to make one term:
Example: $7 \mathbf{x}+\mathbf{x}=8 \mathbf{x}$

## Unlike Terms

If they are not like terms, they are called "Unlike Terms":

| Terms |  | Why are they "Unlike Terms" |
| :--- | :--- | :--- | :--- |
|  | $\leftarrow$ these are all unlike terms |  |
